The "T4T" package

Tools For Typst

v0.4.2 2025-05-12 MIT

An utility package for typst package authors.

Jonas Neugebauer

Tools for Typst (t4t in short) is a utility package for Typst package and template authors. It provides solutions to some recurring tasks in package development.

The package can be imported or any useful parts of it copied into a project. It is perfectly fine to treat t4t as a snippet collection and to pick and choose only some useful functions. For this reason, most functions are implemented without further dependencies.

Hopefully, this collection will grow over time with **Typst** to provide solutions for common problems.

Table of Contents

${\bf Usage}\; {\bf \dots} \qquad {\bf 2}$	II.5 Math functions
I.1 Load from package repository	II.5.1 Command reference 29
(Typst $0.6.0$ and later) 2	II.6 Alias functions
I.2 Manual 2	Index 33
Module reference 4	
II.1 Test functions 4	
II.1.1 Command reference \dots 5	
II.2 Default values 9	
II.2.1 Command reference 9	
II.3 Assertions	
II.3.1 Command reference 14	
II.4 Element helpers 24	
II.4.1 Command reference 24	

Part I

Usage

I.1 Load from package repository (Typst 0.6.0 and later)

For Typst 0.6.0 and later, the package can be imported from the *preview* repository:

```
#import "@preview/t4t:0.4.1": automaton
```

Alternatively, the package can be downloaded and saved into the system dependent local package repository.

Either download the current release from GitHub¹ and unpack the archive into your system dependent local repository folder³ or clone it directly:

```
git clone https://github.com/jneug/typst-tools4typst.git t4t/0.4.1
```

In either case, make sure the files are placed in a subfolder with the correct version number: t4t/0.4.1

After installing the package, just import it inside your typ file:

```
#import "@local/t4t:0.4.1": automaton
```

I.2 Manual

The manual is created using TIDY⁵ with the Mantys⁷ template.

¹https://github.com/jneug/typst-tools4typst²

²https://github.com/jneug/typst-tools4typst

³https://github.com/typst/packages#local-packages⁴

⁴https://github.com/typst/packages#local-packages

⁵https://github.com/Mc-Zen/tidy⁶

⁶https://github.com/Mc-Zen/tidy

⁷https://github.com/jneug/typst-mantys⁸

⁸https://github.com/jneug/typst-mantys

I Usage I.2 Manual

TIDY will be loaded from the package repository while Mantys needs to be installed manually into the local package repository. Refer to the Mantys manual for further information.

The manual doubles as a test suite by adding simple tests to the docstring of each function.

Part II

Module reference

II.1 Test functions

```
#import "@preview/t4t:0.2.0": test
```

These functions provide shortcuts to common tests like #test.eq. Some of these are not shorter than writing pure typst code (e.g. a == b), but can easily be used in .any() or .find() calls:

```
1  // check all values for none
2  if some-array.any(is-none) {
3    ...
4  }
5
6  // find first not none value
7  let x = (none, none, 5, none).find(not-none)
8
9  // find position of a value
10 let pos-bar = args.pos().position(test.eq.with("|"))
```

There are two exceptions: #is-none and #is-auto. Since keywords can't be used as function names, the test module can't define a function like t4t.is-none(). Therefore the functions #is-none and #is-auto are provided in the base module of t4t:

```
1 #import "@preview/t4t:0.1.4": is-none, is-auto
```

The t4t.is submodule still has these tests, but under different names (#test.n and #test.non for none and #test.a and #test.aut for auto).

II.1.1 Command reference

```
#test.all-of-type #test.is-elem #test.neq
#test.any #test.is-empty #test.none-of-type
#test.any-type #test.is-sequence #test.not-any
#test.eq #test.is-type #test.one-not-none
#test.has #test.neg #test.same-type
```

#test.all-of-type((t), ..(values))

Tests if all of the passed in values have the type t.

```
Argument

type to test against

Argument

..(values)

Values to test.
```

$\#\text{test.any}(\{\text{value}\}, ...\{\text{compare}\}) \rightarrow \boxed{\text{bool}}$

Tests, if any value of .. (compare) is equal to (value).

See cmd:test.is-empty for an explanation what *empty* means.

```
Argument (value) any value to test
```

#test.any-type((value), ..(types))

Tests if types (value) is any one of types.

```
Argument (value) any value to test

Argument ...(types) str
```

$\#\text{test.eq}(\{\text{compare}\}, \{\text{value}\}) \rightarrow \boxed{\text{bool}}$

type names to check against

Tests if values (compare) and (value) are equal.

```
Argument (compare) any
```

```
first value

Argument
(value)
second value
```

$\#\text{test.has}(\{\text{value}\}, ...\{\text{keys}\}) \rightarrow \boxed{\text{bool}}$

Tests if (value) contains all the passed .. (keys).

Either as keys in a dictionary or elements in an array. If (value) is neither of those types, false is returned.

```
Argument
(value)
value to test

Argument
..(keys)
any
keys or values to look for
```

#test.is-elem((func), (value))

1 #test.is-elem(raw, some_content)

Tests if (value) is a content element with value.func() == func.

If func is a str, (value) will be compared to repr(value.func()), instead. Both of these effectively do the same:

```
2 #test.is-elem("raw", some_content)

Argument

(func)

element function
```

```
Argument (value) any value to test
```

#test.is-empty((value)) → bool

Tests, if $\langle value \rangle$ is empty.

A value is considered *empty* if it is an empty array, dictionary or str, or the value none.

```
Argument (value) any value to test
```

#test.is-sequence((value))

Tests if (value) is a sequence of content.

#test.is-type((t), (value))

Tests if (value) is of type t.

```
Argument
(t)

name of the type

Argument
(value)

any
value to test
```

$\#\text{test.neg}(\{\text{test}\}) \rightarrow \text{function}$

Creates a new test function, that is true, when (test) is false.

Can be used to create negations of tests like:

```
#let not-raw = test.neg(test.is-raw)

Argument
(test)

Test to negate.

function | bool
```

$\#\text{test.neq}((\text{compare}), (\text{value})) \rightarrow \boxed{\text{bool}}$

Tests if (compare) and (value) are not equal.

```
Argument
(compare)
any
First value.

Argument
(value)
any
Second value.
```

#test.none-of-type((t), ..(values))

Tests if none of the passed in values has the type t.

```
Argument

type to test against

Argument

..(values)

Values to test.
```

$\#\text{test.not-any}(\{\text{value}\}, ...\{\text{compare}\}) \rightarrow \text{bool}$

Tests if (value) is not equals to any one of the other passed in values.

```
Argument
(value)
value to test

Argument
..(compare)
any
values to compare to
```

$\#\text{test.one-not-none}(..\langle\text{values}\rangle) \rightarrow \boxed{\text{bool}}$

Tests, if at least one value in (values) is not equal to none.

Useful for checking mutliple optional arguments for a valid value:

#test.same-type(..(values))

Tests if all passed in values have the same type.

```
Argument
..(values)

Values to test.
```

II.2 Default values

```
#import "@preview/t4t:0.2.0": def
```

These functions perform a test to decide if a given value is *invalid*. If the test passes, the default is returned, the value otherwise.

Almost all functions support an optional do argument, to be set to a function of one argument, that will be applied to the value if the test fails. For example:

```
1
   // Sets date to a datetime from an optional
2
   // string argument in the format "YYYY-MM-DD"
  let date = def.if-none(
3
     datetime.today(), // default
4
                        // passed in argument
5
     passed date,
     do: (d) => {
6
                        // post-processor
       d = d.split("-")
7
8
       datetime(year=d[0], month=d[1], day=d[2])
9
10 )
```

II.2.1 Command reference

```
#def.as-arr #def.if-auto #def.if-none
#def.if-any #def.if-empty #def.if-not-any
#def.if-arg #def.if-false #def.if-true
```

```
#def.as-arr(..(values))
```

Always returns an array containing all values. Any arrays in (values) are unpacked into the resulting array.

This is useful for arguments, that can have one element or an array of elements:

```
1 #def.as-arr(author).join(", ")
#def.if-any((value), (def): none, (do): none, ..(compare))
Returns (def) if (value) is equal to any value in compare, (value) otherwise.

1 #def.if-any(
2 thickness, // value
3 none, auto, // ...compare
```

```
4 def: 1pt,  // default
5 )
```

If (value) is in compare and (do) is set to a function, (value) is passed to (do), before being returned.

```
– Argument –
                                                                         any
(value)
 value to test
Argument —
(def): none
                                                                         any
 The default value.
– Argument —
(do): none
                                                                    function
 Post-processor for (value): (any)→ any
– Argument -
..(compare)
                                                                         any
 list of values to compare (value) to
```

#def.if-arg((key), (args), (def): none, (do): none)

Returns (default) if key is not an existing key in args.named(), args.named().at(key) otherwise.

If (value) is not in args and (do) is set to a function, the value is passed to (do), before being returned.

```
Argument
(key)
key to look for

Argument
(args)
arguments
arguments
to test

Argument
(def): none
any
```

```
Argument

(do): none

Post-processor for (value): (any)→ any
```

#def.if-auto((value), (def): none, (do): none)

Returns (default) if (value) is auto, (value) otherwise.

If (value) is not auto and (do) is set to a function, (value) is passed to (do), before being returned.

```
Argument
(value)

The value to test.

Argument
(def): none

A default value.

Argument
(do): none

Post-processor for (value): (any)→ any
```

#def.if-empty((value), (def): none, (do): none)

Returns (default) if (value) is empty, (value) otherwise.

If (value) is not empty and (do) is set to a function, (value) is passed to (do), before being returned.

Depends on test.is-empty(). See there for an explanation of *empty*.

```
Argument
(value)
value to test

Argument
(def): none
The default value.

Argument
(do): none
Post-processor for (value): (any) → any
```

#def.if-false((test), (value), (def): none, (do): none)

Returns (default) if (test) is false, (value) otherwise.

If (test) is true and (do) is set to a function, (value) is passed to (do), before being returned.

```
– Argument –
   (test)
                                                                            bool
     A test result.
    – Argument –
   (value)
                                                                            any
     The value to test.
    - Argument -
   (def): none
                                                                            any
     The default value.
    – Argument –
   (do): none
                                                                       function
     Post-processor for (value): (any)→ any
#def.if-none((value), (def): none, (do): none)
  Returns (default) if (value) is none, (value) otherwise.
  If (value) is not none and (do) is set to a function, (value) is passed to (do),
  before being returned.
    Argument —
```

```
Argument (value) any
The value to test.
```

```
Argument (def): none any

The default value.
```

```
Argument

(do): none

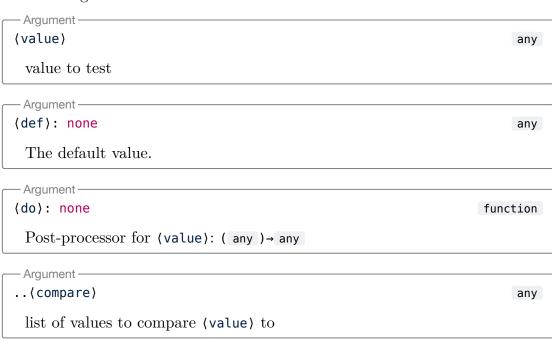

Post-processor for (value): (any)→ any
```

```
#def.if-not-any((value), (def): none, (do): none, ..(compare))
```

Returns (default) if (value) is not equal to any value in compare, (value) otherwise.

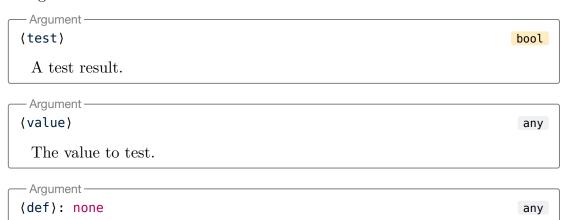

```
1 #def.if-not-any(
2 left, right, top, bottom, // ..compare
3 left, // default
4 position // value
5 )
```

If (value) is in compare and (do) is set to a function, (value) is passed to (do), before being returned.

#def.if-true((test), (value), (def): none, (do): none)
Returns (default) if (test) is true, (value) otherwise.

If (test) is false and (do) is set to a function, (value) is passed to (do), before being returned.

The default value.

—Argument—

(do): none function

Post-processor for (value): (any)→ any

II.3 Assertions

```
#import "@preview/t4t:0.2.0": assert
```

This submodule overloads the default #assert function and provides more asserts to quickly check if given values are valid. All functions use assert in the background.

Since a module in Typst is not callable, the assert function is now available as #assert.that. #assert.eq and #assert.ne work as expected.

All assert functions take an optional argument (message) to set the error message for a failed assertion.

II.3.1 Command reference

```
#assert.all-of-type
                           #assert.ne
                                                      #assert.not-any-type
#assert.any
                           #assert.new
                                                      #assert.not-empty
#assert.any-type
                           #assert.no-named
                                                      #assert.not-none
#assert.eq
                           #assert.no-pos
                                                      #assert.that
                                                      #assert.that-not
#assert.has-named
                           #assert.none-of-type
#assert.has-pos
                           #assert.not-any
```

```
Argument (t)
```

The type to test against.

```
Argument
..(values)

Values to test.
```

```
#assert.any((value), (message): (..a) => "Value should be one of " +
repr(a.pos().slice(1)) + ". Got " + repr(a.pos().first()), ..(values))
Assert that (value) is any one of (values).
```

Tests

```
Argument (value) any Value to compare.
```

```
Argument

(message): (..a) => "Value should be one of " + repr(a.pos().slice(1))

+ ". Got " + repr(a.pos().first())

A message to show if the assertion fails.
```

```
Argument
..(values)

A set of values to compare (value) to.
```

```
#assert.any-type((value), (message): (..a) => (
    "Value should have any type of "
      + repr(a.pos().slice(1))
      + ". Got "
      + repr(a.pos().first())
      + " ("
      + str(type(a.pos().first()))
      + ")"
  ), ..(types))
  Assert that (value)s type is any one of (types).

Argument —

   (value)
                                                                         any
     Value to compare.
    – Argument —
   (message): (..a) => (
        "Value should have any type of "
          + repr(a.pos().slice(1))
          + ". Got "
          + repr(a.pos().first())
          + " ("
          + str(type(a.pos().first()))
          + ")"
                                                               str function
     )
     A message to show if the assertion fails.
    – Argument -
    ..(types)
                                                                         str
     A set of types to compare the type of value to.
\#assert.eq((a), (b), (message): (a, b) => "Value" + repr(a) + " was not
equal to " + repr(b))
  Asserts that two values are equal.
    Argument —
   (a)
                                                                         any
     First value.

Argument -

   (b)
                                                                         any
```

```
Second value.
    - Argument -
   (message): (a, b) => "Value " + repr(a) + " was not equal to " + repr(b)
   str function
     A message to show if the assertion fails.
#assert.has-named((args), (names): none, (strict): false, (message): (..a)
=> {
    let names = a.named().at("names", default: ())
    if names == () {
      "Missing named arguments."
    } else {
      let named = a.named()
      let keys = named.keys()
      names = names.filter(k => k != "names" and k not in keys)
      "Missing named arguments: " + names.join(", ")
    }
  })
  Assert that (args) has named arguments.
  If (n) is a value greater zero, exactly (n) named arguments are required.
  Otherwise, at least one argument is required.
    – Argument -
   (args)
                                                                   arguments
     The arguments to test.
    - Argument —
                                                                array none
   (names): none
     An array with required keys or none.
    - Argument —
   (strict): false
                                                                       bool
     If true, only keys in (names) are allowed.
    Argument —
   (message): (..a) => {
       let names = a.named().at("names", default: ())
       if names == () {
```

"Missing named arguments."

```
} else {
    let named = a.named()
    let keys = named.keys()
    names = names.filter(k => k != "names" and k not in keys)
    "Missing named arguments: " + names.join(", ")
}

A message to show if the assertion fails.
```

```
#assert.has-pos((args), (n): none, (message): (n: none, ..a) => {
    if n == none {
        "At least one positional argument required."
    } else {
        "Exactly " + str(n) + " positional arguments required, got "
+ repr(a.pos())
    }
})
```

Assert that (args) has positional arguments.

If (n) is a value greater zero, exactly (n) positional arguments are required. Otherwise, at least one argument is required.

```
1 #let add(..args) = {
2   assert.has-pos(args)
3   return args.pos().fold(0, (s, v) => s+v)
4 }
```

```
Argument (args) arguments

The arguments to test.
```

```
Argument

(n): none

The mandatory number of positional arguments or none.
```

```
Argument

(message): (n: none, ..a) => {

  if n == none {

    "At least one positional argument required."
```

```
} else {
    "Exactly " + str(n) + " positional arguments required, got "
+ repr(a.pos())
    }
}
A message to show if the assertion fails.
```

```
#assert.ne((a), (b), (message): (a, b) => "Value " + repr(a) + " was equal
to " + repr(b))
```

Asserts that two values are not equal.

```
Argument any
First value.
```

```
Argument (b)
Second value.
```

```
Argument

(message): (a, b) => "Value " + repr(a) + " was equal to " + repr(b)

str | function

A message to show if the assertion fails.
```

```
#assert.new((test), (message): "")
```

Creates a new assertion from test.

The new assertion will take any number of values and pass them to test. test should return a bool.

```
1 #let assert-numeric = assert.new(t4t.is-num)
2
3 #let diameter(radius) = {
4   assert-numeric(radius)
5   return 2*radius
6 }
```

 $8.6 \ 4$

```
– Argument –
   (test)
                                                                   function
     A test function: (.. any )→ bool
#assert.no-named((args), (message): (..a) => "Unexpected named arguments:
" + repr(a.named()))
  Assert that (args) has no named arguments.
   Argument —
   (args)
                                                                  arguments
     The arguments to test.
   (message): (..a) => "Unexpected named arguments: " + repr(a.named())
   str function
     A message to show if the assertion fails.
#assert.no-pos((args), (message): (..a) => "Unexpected positional"
arguments: " + repr(a))
  Assert that (args) has no positional arguments.
    1 #let new-dict(..args) = {
    2
         assert.no-pos(args)
    3
      return args.named()
    4 }
   – Argument –
   (args)
                                                                  arguments
     The arguments to test.
   (message): (..a) => "Unexpected positional arguments: " + repr(a) str
   function
     A message to show if the assertion fails.
```

```
#assert.none-of-type((t), (message): (..a) => (
    "Values may not be of type "
      + repr(a.pos().first())
      + ". Got "
      + repr(a.pos().slice(1))
      + " / "
      + repr(a.pos().slice(1).map(type))
  ), ..(values))
  Assert that none of the (values) are of type (t).
   (t)
                                                                       str
     The type to test against.
    Argument —
   (message): (..a) => (
        "Values may not be of type "
         + repr(a.pos().first())
         + ". Got "
         + repr(a.pos().slice(1))
         + " / "
         + repr(a.pos().slice(1).map(type))
                                                             str function
     A message to show if the assertion fails.
    - Argument -
   ..(values)
                                                                        any
     Values to test.
#assert.not-any((value), (message): (..a) => "Value should not be one of "
+ repr(a.pos().slice(1)) + ". Got " + repr(a.pos().first()), ..(values))
  Assert that (value) is not any one of (values).
    – Argument –
   (value)
                                                                        any
     Value to compare.
    – Argument –
                                                                 of
                (..a) => "Value
                                       should not
                                                      be
                                                           one
   (message):
   repr(a.pos().slice(1)) + ". Got " + repr(a.pos().first()) str | function
     A message to show if the assertion fails.
```

```
Argument –

   ..(values)
                                                                        any
     A set of values to compare value to.
#assert.not-any-type((value), (message): (..a) => (
    "Value should not have any type of "
      + repr(a.pos().slice(1))
      + ". Got "
      + repr(a.pos().first())
      + " ("
      + str(type(a.pos().first()))
      + ")"
  ), ..(types))
  Assert that (value)s type is not any one of (types).
    Argument —
   (value)
                                                                        any
     Value to compare.

Argument —

   (message): (..a) => (
        "Value should not have any type of "
         + repr(a.pos().slice(1))
          + ". Got "
         + repr(a.pos().first())
          + " ("
          + str(type(a.pos().first()))
          + ")"
                                                              str function
     A message to show if the assertion fails.
    – Argument –
    ..(types)
                                                                        str
     A set of types to compare the type of value to.
#assert.not-empty((value), (message): (v, ..a) => {
    "Value may not be empty. Got " + repr(v)
  })
  Assert that (value) is not empty.
  Depends on test.is-empty(). See there for an explanation of empty.
```

```
– Argument –
   (value)
                                                                         any
     The value to test.
    - Argument —
   (message): (v, ..a) => {
        "Value may not be empty. Got " + repr(v)
                                                               str function
     A message to show if the assertion fails.
#assert.not-none((message): (..a) => "Values should not be none. Got " +
repr(a), ..(values))
  Asserts that not one of (values) is none. Positional and named arguments are
  tested if provided. For named key-value pairs the value is tested.
    Argument —
   (message): (..a) => "Values should not be none. Got " + repr(a) str
   function
     A message to show if the assertion fails.
    Argument —
   ..(values)
                                                                         any
     The values to test.
#assert.that((test), (message): "Test returned false, should be true.")
  Asserts that (test) is true. See #assert.
    - Argument —
   (test)
                                                                        bool
     Assertion to test.
    Argument —
   (message): "Test returned false, should be true." str | function
     A message to show if the assertion fails.
#assert.that-not((test), (message): "Test returned true, should be false.")
  Asserts that (test) is false.
    - Argument —
   (test)
                                                                        bool
     Assertion to test.
```

```
Argument

(message): "Test returned true, should be false."

A message to show if the assertion fails.
```

#neq

Alias for cmd:assert.ne

II.4 Element helpers

```
#import "@preview/t4t:0.2.0": get
```

This submodule is a collection of functions, that mostly deal with content elements and *get* some information from them. Though some handle other types like dictionaries.

II.4.1 Command reference

```
#get.args #get.inset-dict #get.text
#get.dict #get.stroke-dict #get.x-align
#get.dict-merge #get.stroke-paint #get.y-align
#get.inset-at #get.stroke-thickness
```

```
\#get.args((args), (prefix): "") \rightarrow dictionary
```

Creats a function to extract values from an argument sink (args).

The resulting function takes any number of positional and named arguments and creates a dictionary with values from <code>args.named()</code>. Positional arguments to the function are only present in the result, if they are present in <code>args.named()</code>. Named arguments are always present, either with their value from <code>args.named()</code> or with the provided value as a fallback.

If a (prefix) is specified, only keys with that prefix will be extracted from (args). The resulting dictionary will have all keys with the prefix removed, though.

```
1
   #let my-func( ..options, title ) = block(
2
        ..get.args(options)(
            "spacing", "above", "below",
3
4
           width: 100%
5
       )
6
   ] (
7
       #text(..get.args(options, prefix:"text-")(
            fill:black, size:0.8em
8
9
        ), title)
10 ]
11
12 #my-func(
13
       width: 50%,
       text-fill: red, text-size: 1.2em
14
15 )[#lorem(5)]
```

```
Argument (args) arguments
Argument of a function.
```

```
Argument

(prefix): ""

A prefix for the argument keys to extract.
```

```
#get.dict(..(dicts)) → dictionary
Create a new dictionary from (
    metadata(value: (func: (...) => ..., args: (), kind: "barg")),
).
```

All named arguments are stored in the new dictionary as is. All positional arguments are grouped in key/value-pairs and inserted into the dictionary:

```
#get.dict("a", 1, "b", 2, "c", d:4, e:5)

// gives (a:1, b:2, c:none, d:4, e:5)
```

```
Argument
..(dicts)

Values to merge into the dictionary.
```

$\#get.dict-merge(..(dicts)) \rightarrow dictionary$

Recursivley merges the passed in dictionaries.

```
#get.dict-merge(
    (a: 1, b: 2),
    (a: (one: 1, two:2)),
    (a: (two: 4, three:3))
)

// gives (a:(one:1, two:4, three:3), b: 2)
```

Based on work by @johannes-wolf for johannes-wolf/typst-canvas9.

```
Argument
..(dicts)

Dictionaries to merge.
```

#get.inset-at((direction), (inset), (default): 0pt) \rightarrow length

Returns the inset (or outset) in a given (direction), ascertained from (inset).

```
Argument

(direction) str | alignment

The direction to get.
```

```
(inset) length | dictionary

The inset value.
```

```
Argument (default): Opt

A default value.
```

#get.inset-dict((inset), ..(overrides)) → dictionary

Creates a dictionary usable as an inset (or outset) argument.

The resulting dictionary is guaranteed to have the keys top, left, bottom and right. If inset is a dictionary itself, all key/value-pairs are copied to the resulting inset. Any named arguments in overrides will override the previous values.

⁹https://github.com/johannes-wolf/typst-canvas/

II Module reference II.4 Element helpers

```
Argument
(inset)

The base inset value.

Argument
..(overrides)

Overrides for the inset.
```

$\#get.stroke-dict((stroke), ..(overrides)) \rightarrow dictionary$

Converts (stroke) into a dictionary.

The dictionary will always have the keys thickness, paint, dash, cap and join. If stroke is a dictionary itself, all key/value-pairs are copied to the resulting stroke. Any named arguments in overrides will override the previous values:

```
#let stroke = get.stroke-dict(2pt + red, cap:"square")

Argument
(stroke)

A stroke value.

Argument
..(overrides)

Overrides for the stroke.
```

#get.stroke-paint((stroke), (default): black) → color

Returns the color of (stroke). If no color information is available, default is used.

Compared to stroke.paint, this function will return a color for any possible stroke definition (length, dictionary ...).

Based on work by @PgBiel for PgBiel/typst-tablex¹⁰.

```
Argument (stroke) length | color | dictionary | stroke

The stroke value.

Argument (default): black color
```

¹⁰https://github.com/PgBiel/typst-tablex

A default color to use.

```
#get.stroke-thickness((stroke), (default): 1pt) → length
```

Returns the thickness of (stroke). If no thickness information is available, default is used.

Compared to stroke.thickness, this function will return a thickness for any possible stroke definition (length, dictionary ...).

```
Argument
(stroke) length | color | dictionary | stroke
The stroke value.
```

```
Argument
(default): 1pt

A default thickness to use.
```

```
#get.text((element), (sep): "") \rightarrow str
```

Recursively extracts the text content of (element).

If (element) has children, all child elements are converted to text and joined with (sep).

- element (any)
- sep (str, content)

```
\#get.x-align((align), (default): left) \rightarrow alignment
```

Returns the alignment along the x-axis from (align).

If none is present, (default) is returned.

```
get.x-align(top + center) // center
```

```
(align) alignment | 2d alignment | The alignment to get the x-alignment from.
```

```
Argument

(default): left

A default alignment.
```

```
#get.y-align((align), (default): top) \rightarrow alignment
```

Returns the alignment along the y-axis from (align).

If none is present, (default) is returned.

```
get.y-align(top + center) // top
```

```
Argument (align) alignment | 2d alignment |
The alignment to get the y-alignment from.
```

```
Argument (default): top alignment
```

A default alignment.

II.5 Math functions

```
#import "@preview/t4t:0.2.0": math
```

Some functions to complement the native calc module.

II.5.1 Command reference

```
#math.clamp #math.map
#math.lerp #math.minmax
```

```
#math.clamp((min), (max), (value)) \rightarrow any
```

Clamps a value between min and max.

In contrast to #clamp this function works for other values than numbers, as long as they are comparable.

```
text-size = math.clamp(0.8em, 1.2em, text-size)
```

Works with any comparable type.

```
Argument

(min) int | float | length | relative length | fraction | ratio

Maximum for value.
```

```
Argument
(value) int | float | length | relative length | fraction | ratio
The value to clamp.
```

```
#math.lerp(\langle min \rangle, \langle max \rangle, \langle t \rangle) \rightarrow int | float | length | relative length | fraction | ratio
```

Calculates the linear interpolation of t between min and max.

t should be a value between 0 and 1, but the interpolation works with other values, too. To constrain the result into the given interval, use cmd:math.clamp

```
#let width = math.lerp(0%, 100%, x)
#let width = math.lerp(0%, 100%, math.clamp(0, 1, x))
```

```
Argument

(min) int | float | length | relative length | fraction | ratio

Minimum for value.
```

```
Argument (max) int | float | length | relative length | fraction | ratio | Maximum for value.
```

```
Argument (t) float

Interpolation parameter .
```

Maps a value from the interval [min, max] into the interval [range-min, range-max]:

```
#let text-weight = int(math.map(8pt, 16pt, 400, 800, text-size))
```

The types of min, max and value and the types of range-min and range-max have to be the same.

II Module reference II.5 Math functions

```
Argument
(min) int | float | length | relative length | fraction | ratio

Maximum of the initial interval.
```

```
Argument
(range-min) int | float | length | relative length | fraction | ratio

Maximum of the target interval.
```

```
Argument
(value) int | float | length | relative length | fraction | ratio
The value to map.
```

```
#math.minmax((a), (b)) \rightarrow int | float | length | relative length | fraction | ratio
```

Returns an array with the minimum of **a** and **b** as the first element and the maximum as the second:

```
#let (min, max) = math.minmax(a, b)
```

Works with any comparable type.

```
Argument
(a) int | float | length | relative length | fraction | ratio
First value.
```

```
Argument
(b) int | float | length | relative length | fraction | ratio
Second value.
```

II.6 Alias functions

```
#import "@preview/t4t:0.2.0": alias
```

Some of the native Typst function as aliases, to prevent collisions with some common argument namens.

For example using (numbering) as an argument is not possible if the value is supposed to be passed to the #numbering function. To still allow argument names,

II Module reference II.6 Alias functions

that are in line with the common Typst names (like type, align ...), these alias functions can be used:

```
1 #let excercise( no, numbering: "1)" ) = [
2 Exercise #alias.numbering(numbering, no)
3 ]
```

The following functions have aliases right now:

- numbering
- align
- type
- label
- text

- raw
- table
- list
- enum

- terms
- grid
- stack
- columns
